Basic Problem (Solving Diophantine Equations)

Setup

Let $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$ be polynomials.

Let R be a ring (e.g., $R = \mathbb{Z}, \mathbb{Q}$).

Problem

Describe the set

$$V(f_1, \dots, f_m) = \{(a_1, \dots, a_n) \in R^n : \forall i, f_i(a_1, \dots, a_n) = 0\}.$$

Fact

Solving Diophantine equations is hard.

Hilbert's Tenth Problem

The ring $R = \mathbb{Z}$ is especially hard.

Hilbert's Tenth Problem

The ring $R = \mathbb{Z}$ is especially hard.

Theorem (Davis–Putnam–Robinson 1961, Matijasevič 1970)

There does not exist an algorithm solving the following problem:

input: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$;

output: YES / NO according to whether the set

$$\{(a_1, \dots, a_n) \in \mathbb{Z}^n : \forall i, f_i(a_1, \dots, a_n) = 0\}$$

is non-empty.

Hilbert's Tenth Problem

The ring $R = \mathbb{Z}$ is especially hard.

Theorem (Davis–Putnam–Robinson 1961, Matijasevič 1970)

There does not exist an algorithm solving the following problem:

input: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$;

output: YES / NO according to whether the set

$$\{(a_1, \dots, a_n) \in \mathbb{Z}^n : \forall i, f_i(a_1, \dots, a_n) = 0\}$$

is non-empty.

This is also known to be true for many rings (e.g., $R = \mathbb{C}, \mathbb{R}, \mathbb{F}_q, \mathbb{Q}_p, \mathbb{C}(t)$).

Hilbert's Tenth Problem

The ring $R = \mathbb{Z}$ is especially hard.

Theorem (Davis–Putnam–Robinson 1961, Matijasevič 1970)

There does not exist an algorithm solving the following problem:

input: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$;

output: YES / NO according to whether the set

$$\{(a_1, \dots, a_n) \in \mathbb{Z}^n : \forall i, f_i(a_1, \dots, a_n) = 0\}$$

is non-empty.

This is also known to be true for many rings (e.g., $R = \mathbb{C}, \mathbb{R}, \mathbb{F}_q, \mathbb{Q}_p, \mathbb{C}(t)$).
This is still open for many other rings (e.g., $R = \mathbb{Q}$).

Fermat's Last Theorem

Theorem (Wiles; Taylor)

For primes $p \geq 3$ the only integer solutions to the equation

$$x^p + y^p = z^p$$

are integer multiples of the triples

$$(0, 0, 0), \quad (\pm 1, \mp 1, 0), \quad \pm(1, 0, 1), \quad \pm(0, 1, 1).$$

Fermat's Last Theorem

Theorem (Wiles; Taylor)

For primes $p \geq 3$ the only integer solutions to the equation

$$x^p + y^p = z^p$$

are integer multiples of the triples

$$(0, 0, 0), \quad (\pm 1, \mp 1, 0), \quad \pm(1, 0, 1), \quad \pm(0, 1, 1).$$

This took 300 years to prove!

Fermat's Last Theorem

Theorem (Wiles; Taylor)

For primes $p \geq 3$ the only integer solutions to the equation

$$x^p + y^p = z^p$$

are integer multiples of the triples

$$(0, 0, 0), \quad (\pm 1, \mp 1, 0), \quad \pm(1, 0, 1), \quad \pm(0, 1, 1).$$

This took 300 years to prove!

Basic Problem: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$

Qualitative:

- Does there **exist** a solution?
- Do there exist **infinitely many** solutions?
- Does the set of solutions have some **extra structure** (e.g., geometric structure, group structure).

Basic Problem: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$

Qualitative:

- Does there **exist** a solution?
- Do there exist **infinitely many** solutions?
- Does the set of solutions have some **extra structure** (e.g., geometric structure, group structure).

Quantitative

- How **many** solutions are there?
- How **large** is the **smallest** solution?
- How can we explicitly **find** all solutions? (With proof?)

Basic Problem: $f_1, \dots, f_m \in \mathbb{Z}[x_1, \dots, x_n]$

Qualitative:

- Does there **exist** a solution?
- Do there exist **infinitely many** solutions?
- Does the set of solutions have some **extra structure** (e.g., geometric structure, group structure).

Quantitative

- How **many** solutions are there?
- How **large** is the **smallest** solution?
- How can we explicitly **find** all solutions? (With proof?)

Implicit question

- Why do equations **have** (or fail to have) solutions?
- Why do some have **many** and some have **none**?
- What **underlying mathematical structures** control this?

Example: Pythagorean triples

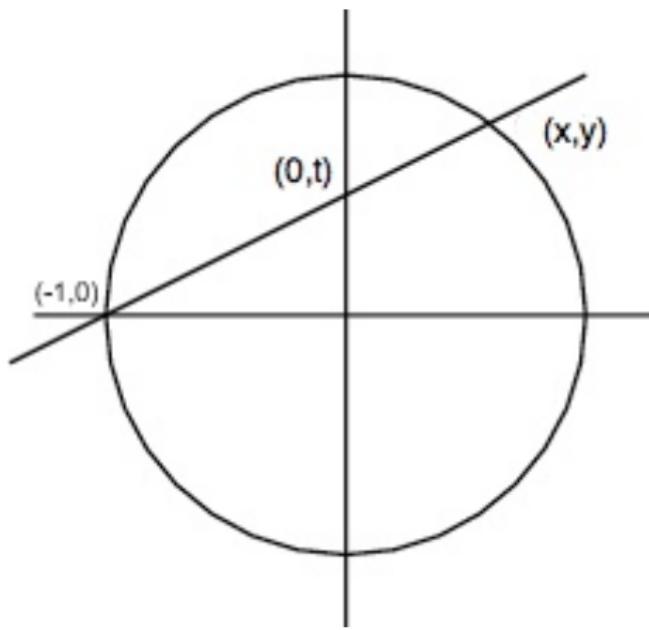

Lemma

The equation

$$x^2 + y^2 = z^2$$

has infinitely many non-zero coprime solutions.

Pythagorean triples

$$\text{Slope} = t = \frac{y}{x+1}$$

$$x = \frac{1-t^2}{1+t^2}$$

$$y = \frac{2t}{1+t^2}$$

Pythagorean triples

Lemma

The solutions to

$$a^2 + b^2 = c^2$$

(with $c \neq 0$) are all multiples of the triples

$$a = 1 - t^2$$

$$b = 2t$$

$$c = 1 + t^2$$

The Mordell Conjecture

Example

The equation $y^2 + x^2 = 1$ has infinitely many solutions.

The Mordell Conjecture

Example

The equation $y^2 + x^2 = 1$ has infinitely many solutions.

Theorem (Faltings)

For $n \geq 5$, the equation

$$y^2 + x^n = 1$$

has only finitely many solutions.

The Mordell Conjecture

Example

The equation $y^2 + x^2 = 1$ has infinitely many solutions.

Theorem (Faltings)

For $n \geq 5$, the equation

$$y^2 + x^n = 1$$

has only finitely many solutions.

Theorem (Faltings)

For $n \geq 5$, the equation

$$y^2 = f(x)$$

has only finitely many solutions if $f(x)$ is squarefree, with degree > 4 .

Fermat Curves

Question

Why is Fermat's last theorem believable?

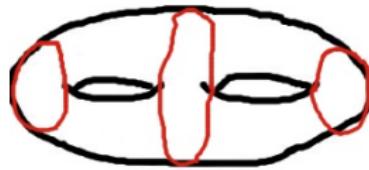

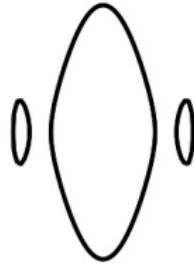

- ① $x^n + y^n - z^n = 0$ looks like a surface (3 variables)
- ② $x^n + y^n - 1 = 0$ looks like a curve (2 variables)

Mordell Conjecture

Example

$$y^2 = -(x^2 - 1)(x^2 - 2)(x^2 - 3)$$

This is a cross section of a two holed torus.

The **genus** is the number of holes.

Conjecture (Mordell, 1922)

A curve of genus $g \geq 2$ has only finitely many rational solutions.

Fermat Curves

Question

Why is Fermat's last theorem believable?

- ① $x^n + y^n - z^n = 0$ looks like a surface (3 variables)
- ② $x^n + y^n - 1 = 0$ looks like a curve (2 variables)
- ③ and has genus

$$(n-1)(n-2)/2$$

which is ≥ 2 iff $n \geq 4$.

Fermat Curves

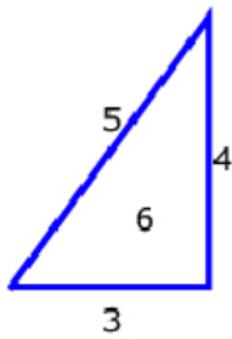

Question

What if $n = 3$?

- ① $x^3 + y^3 - 1 = 0$ is a curve of genus $(3 - 1)(3 - 2)/2 = 1$.
- ② We were lucky; $Ax^3 + By^3 = Cz^3$ can have infinitely many solutions.

Congruent number problem

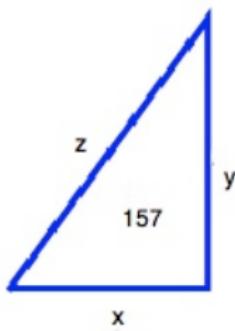

$$x^2 + y^2 = z^2, xy = 2 \cdot 6$$

$$3^2 + 4^2 = 5^2, \quad 3 \cdot 4 = 2 \cdot 6$$

Congruent number problem

$$x^2 + y^2 = z^2, xy = 2 \cdot 157$$

Assume the Birch–Swinnerton-Dyer conjectures

If you assume \$1,000,000 worth of conjectures, then the equations

$$x^2 + y^2 = z^2, \quad xy = 2 \cdot 157$$

have **infinitely many** solutions. **How large** is the smallest solution? How many **digits** does the smallest solution have?

Assume the Birch–Swinnerton-Dyer conjectures

If you assume \$1,000,000 worth of conjectures, then the equations

$$x^2 + y^2 = z^2, \quad xy = 2 \cdot 157$$

have **infinitely many** solutions. **How large** is the smallest solution? How many **digits** does the smallest solution have?

$$x = \frac{157841 \cdot 4947203 \cdot 52677109576}{2 \cdot 3^2 \cdot 5 \cdot 13 \cdot 17 \cdot 37 \cdot 101 \cdot 17401 \cdot 46997 \cdot 356441}$$

$$y = \frac{2 \cdot 3^2 \cdot 5 \cdot 13 \cdot 17 \cdot 37 \cdot 101 \cdot 157 \cdot 17401 \cdot 46997 \cdot 356441}{157841 \cdot 4947203 \cdot 52677109576}$$

$$z = \frac{20085078913 \cdot 1185369214457 \cdot 942545825502442041907480}{2 \cdot 3^2 \cdot 5 \cdot 13 \cdot 17 \cdot 37 \cdot 101 \cdot 17401 \cdot 46997 \cdot 356441 \cdot 157841 \cdot 4947203 \cdot 52677109576}$$

Assume the Birch–Swinnerton-Dyer conjectures

- Expected time until ‘heat death’ of universe – **10^{100} years.**

Fermat Surfaces

Conjecture

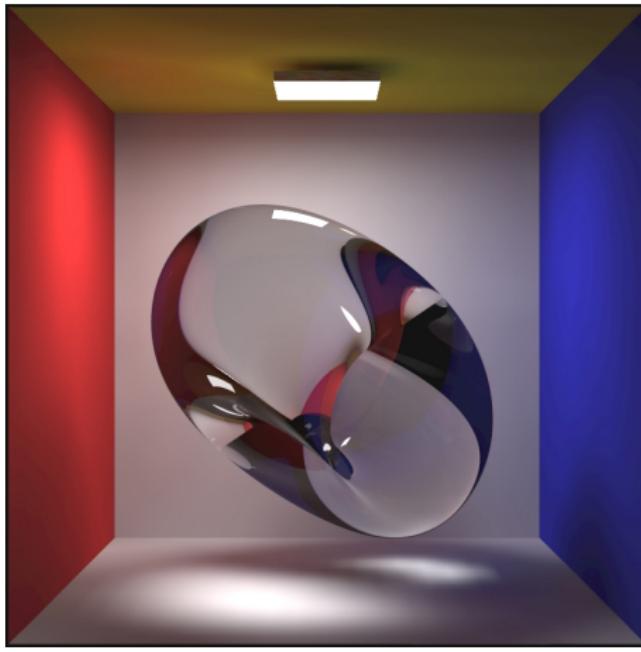

The only solutions to the equation

$$x^n + y^n = z^n + w^n, n \geq 5$$

satisfy $xyzw = 0$ or lie on the lines ‘lines’ $x = z$, $y = w$ (and permutations).

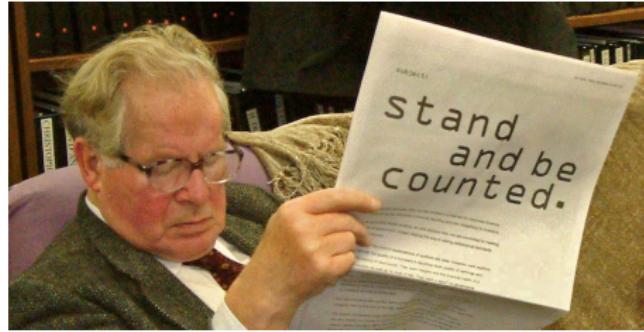

The Swinnerton-Dyer K3 surface

$$x^4 + 2y^4 = 1 + 4z^4$$

The Swinnerton-Dyer K3 surface

$$x^4 + 2y^4 = 1 + 4z^4$$

Two ‘obvious’ solutions – $(\pm 1 : 0 : 0)$.

The Swinnerton-Dyer K3 surface

$$x^4 + 2y^4 = 1 + 4z^4$$

- Two ‘obvious’ solutions – $(\pm 1 : 0 : 0)$.
- The next smallest solutions are $(\pm \frac{1484801}{1169407}, \pm \frac{1203120}{1169407}, \pm \frac{1157520}{1169407})$.

Problem

Find another solution. (Probably impossible.)

Back of envelope calculation

- ① **10^{16} years** to find via brute force.
- ② Age of the universe – **$13.75 \pm .11$ billion years** (roughly **10^{10}**).

“Generalized” Fermat equations

Theorem (Poonen, Schaefer, Stoll)

The coprime integer solutions to $x^2 + y^3 = z^7$ are the 16 triples

$$(\pm 1, -1, 0), \quad (\pm 1, 0, 1), \quad \pm(0, 1, 1),$$

Generalized Fermat Equations

Problem

What are the solutions to the equation $x^a + y^b = z^c$?

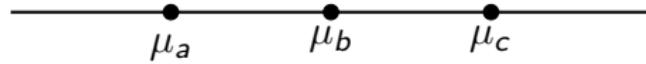

Generalized Fermat Equations

Problem

What are the solutions to the equation $x^a + y^b = z^c$?

Theorem (Darmon and Granville)

Fix $a, b, c \geq 2$. Then the equation $x^a + y^b = z^c$ has only finitely many coprime integer solutions iff $\chi = \frac{1}{a} + \frac{1}{b} + \frac{1}{c} - 1 \leq 0$.

Known Solutions to $x^a + y^b = z^c$ with $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} < 1$

$$1^p + 2^3 = 3^2, \quad 2^5 + 7^2 = 3^4$$

$$7^3 + 13^2 = 2^9, \quad 2^7 + 17^3 = 71^2$$

$$3^5 + 11^4 = 122^2$$

$$17^7 + 76271^3 = 21063928^2$$

$$1414^3 + 2213459^2 = 65^7$$

$$9262^3 + 153122832^2 = 113^7$$

$$43^8 + 96222^3 = 30042907^2$$

$$33^8 + 1549034^2 = 15613^3$$

Known Solutions to $x^a + y^b = z^c$ with $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} < 1$

$$1^p + 2^3 = 3^2, \quad 2^5 + 7^2 = 3^4$$

$$7^3 + 13^2 = 2^9, \quad 2^7 + 17^3 = 71^2$$

$$3^5 + 11^4 = 122^2$$

$$17^7 + 76271^3 = 21063928^2$$

$$1414^3 + 2213459^2 = 65^7$$

$$9262^3 + 153122832^2 = 113^7$$

$$43^8 + 96222^3 = 30042907^2$$

$$33^8 + 1549034^2 = 15613^3$$

Problem (Beal's conjecture)

These are all solutions with $\frac{1}{a} + \frac{1}{b} + \frac{1}{c} - 1 < 0$.

Generalized Fermat Equations – Known Solutions

Faltings' theorem / Mordell's conjecture

Theorem (Faltings, Vojta, Bombieri)

Let X be a smooth curve with genus at least 2. Then $\#X(\mathbb{Q}) < \infty$.

Example

For $g \geq 2$, $y^2 = x^{2g+1} + 1$ has only finitely many solutions with $x, y \in \mathbb{Q}$.

Conjecture (Lang, Vojta)

Let X be a variety of general type. Then $X(\mathbb{Q})$ is not (Zariski) dense.

Uniformity

Problem

- ① Given X , compute $X(\mathbb{Q})$ exactly.
- ② Compute bounds on $\#X(\mathbb{Q})$.

Conjecture (Uniformity)

There exists a constant $N(g)$ such that every smooth curve of genus g over \mathbb{Q} has at most $N(g)$ rational points.

Theorem (Caporaso, Harris, Mazur)

Lang's conjecture \Rightarrow uniformity.

Uniformity numerics

g	2	3	4	5	10	45	g
$B_g(\mathbb{Q})$	642	112	126	132	192	781	$16(g + 1)$

$$y^2 = 82342800x^6 - 470135160x^5 + 52485681x^4 + 2396040466x^3 + 567207969x^2 - 985905640x + 247747600$$

$$x = -3898675687/2462651894$$

$$y = 414541623698393040986922116885/83905238898871602089890028$$

Remark

Elkies studied K3 surfaces of the form

$$y^2 = S(t, u, v)$$

with lots of rational lines, such that S restricted to such a line is a square.

Main Theorem (uniformity for curves of small rank)

Theorem (Katz–Rabinoff–ZB)

Let X be *any* curve of genus g and let $r = \text{rank}_{\mathbb{Z}} \text{Jac}_X(\mathbb{Q})$. Suppose $r < g - 2$. Then

$$\#X(\mathbb{Q}) \leq 84g^2 - 98g + 28$$

Tools

p-adic integration on annuli

comparison of different analytic continuations of *p*-adic integration

Non-Archimedean (Berkovich) structure of a curve [BPR]

Combinatorial restraints coming from the Tropical canonical bundle

Coleman's bound

Theorem (Coleman, 1985)

Let X be a curve of genus g and let $r = \text{rank}_{\mathbb{Z}} \text{Jac}_X(\mathbb{Q})$. Suppose $p > 2g$ is a prime of **good reduction**. Suppose $r < g$. Then

$$\#X(\mathbb{Q}) \leq \#X(\mathbb{F}_p) + 2g - 2.$$

Remark

- ① A modified statement holds for $p \leq 2g$ or for $K \neq \mathbb{Q}$.
- ② This does not prove uniformity (since the first good p might be large).

Tools

p -adic integration and Riemann–Roch

Chabauty's method

(**p -adic integration**) There exists $V \subset H^0(X_{\mathbb{Q}_p}, \Omega_X^1)$ with $\dim_{\mathbb{Q}_p} V \geq g - r$ such that

$$\int_P^Q \omega = 0 \quad \forall P, Q \in X(\mathbb{Q}), \omega \in V.$$

(**Coleman, via Newton Polygons**) Number of zeroes in a residue disc D_P is $\leq 1 + n_P$, where $n_P = \#(\text{div } \omega \cap D_P)$

(**Riemann–Roch**) $\sum n_P = 2g - 2$.

(**Coleman's bound**) $\sum_{P \in X(\mathbb{F}_p)} (1 + n_P) = \#X(\mathbb{F}_p) + 2g - 2$.

Example (from McCallum–Poonen's survey paper)

Example

$$X: y^2 = x^6 + 8x^5 + 22x^4 + 22x^3 + 5x^2 + 6x + 1$$

- ① Points P_t reducing mod 3 to $\tilde{Q} = (0, 1)$ are given by

$$x = 3 \cdot t, \text{ where } t \in \mathbb{Z}_3$$

$$y = \sqrt{x^6 + 8x^5 + 22x^4 + 22x^3 + 5x^2 + 6x + 1} = 1 + x^2 + \dots$$

② $\int_{(0,1)}^{P_t} \frac{xdx}{y} = \int_0^t (x - x^3 + \dots) dx$

p -adic integration

(Chabauty, Coleman) There exists $V \subset H^0(X_{\mathbb{Q}_p}, \Omega_X^1)$ with $\dim_{\mathbb{Q}_p} V \geq g - r$ such that,

$$\int_P^Q \omega = 0 \quad \forall P, Q \in X(\mathbb{Q}), \omega \in V$$

Example

$$X: y^2 = x^6 + 8x^5 + 22x^4 + 22x^3 + 5x^2 + 6x + 1$$

- ① Points reducing mod 3 to $\tilde{Q} = (0, 1)$ are given by

$$x = 3 \cdot t, \text{ where } t \in \mathbb{Z}_3$$

$$y = \sqrt{x^6 + 8x^5 + 22x^4 + 22x^3 + 5x^2 + 6x + 1} = 1 + x^2 + \dots$$

② $\int_{(0,1)}^{P_t} \frac{xdx}{y} = \int_0^t (x - x^3 + \dots) dx$

Chabauty's method

(**p -adic integration**) There exists $V \subset H^0(X_{\mathbb{Q}_p}, \Omega_X^1)$ with $\dim_{\mathbb{Q}_p} V \geq g - r$ such that

$$\int_P^Q \omega = 0 \quad \forall P, Q \in X(\mathbb{Q}), \omega \in V.$$

(**Coleman, via Newton Polygons**) Number of zeroes in a residue disc D_P is $\leq 1 + n_P$, where $n_P = \#(\text{div } \omega \cap D_P)$

(**Riemann–Roch**) $\sum n_P = 2g - 2$.

(**Coleman's bound**) $\sum_{P \in X(\mathbb{F}_p)} (1 + n_P) = \#X(\mathbb{F}_p) + 2g - 2$.

Stoll's hyperelliptic uniformity theorem

Theorem (Stoll, 2013)

Let X be a *hyperelliptic* curve of genus g and let $r = \text{rank}_{\mathbb{Z}} \text{Jac}_X(\mathbb{Q})$. Suppose $r < g - 2$.

Then

$$\#X(\mathbb{Q}) \leq 8(r + 4)(g - 1) + \max\{1, 4r\} \cdot g$$

Tools

p -adic integration on *annuli*

comparison of different analytic continuations of p -adic integration

Main Theorem (uniformity for curves of small rank)

Theorem (Katz–Rabinoff–ZB)

Let X be *any* curve of genus g and let $r = \text{rank}_{\mathbb{Z}} \text{Jac}_X(\mathbb{Q})$. Suppose $r < g - 2$. Then

$$\#X(\mathbb{Q}) \leq 84g^2 - 98g + 28$$

comparison of different analytic continuations of *p*-adic integration

Non-Archimedean (Berkovich) structure of a curve [BPR]

Combinatorial restraints coming from the Tropical canonical bundle

Comments

Corollary ((Partially) effective Manin-Mumford)

There is an effective constant $N(g)$ such that if $g(X) = g$, then

$$\#(X \cap \text{Jac}_{X,\text{tors}})(\mathbb{Q}) \leq N(g)$$

Corollary

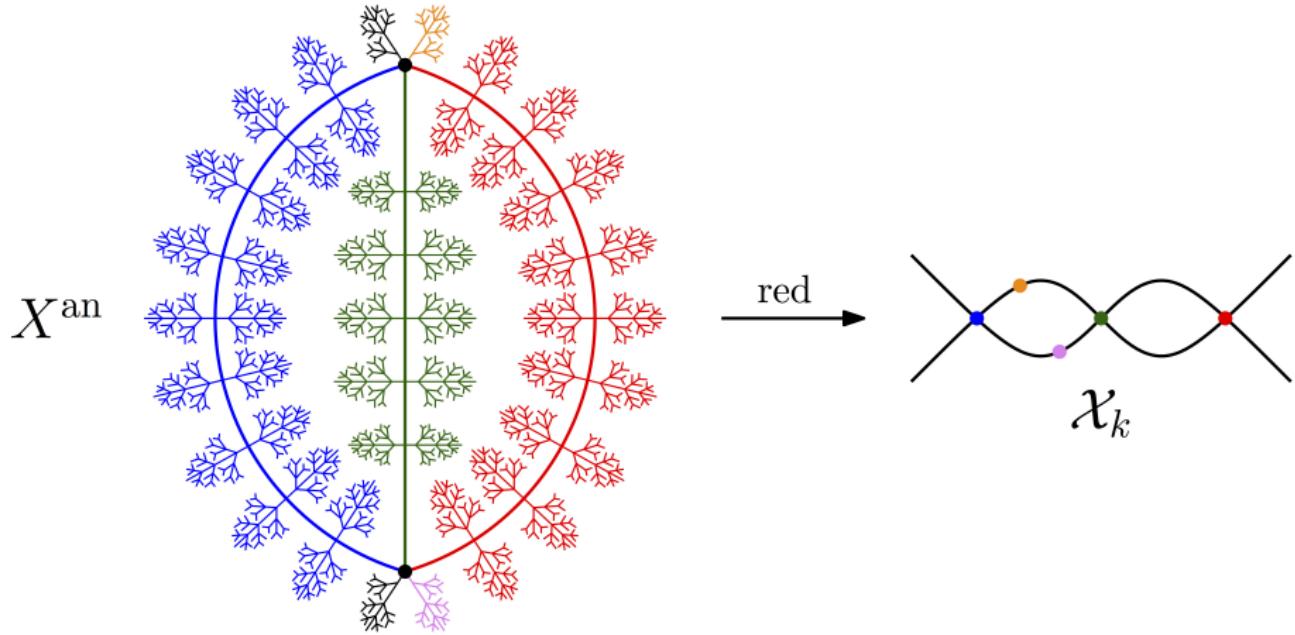

*There is an effective constant $N'(g)$ such that if $g(X) = g > 3$ and X/\mathbb{Q} has **totally degenerate, trivalent** reduction mod 2, then*

$$\#(X \cap \text{Jac}_{X,\text{tors}})(\mathbb{C}) \leq N'(g)$$

The second corollary is a big improvement

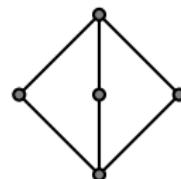

- ① It requires working over a **non-discretely valued** field.
- ② The bound **only depends on the reduction type**.
- ③ Integration over **wide opens** (c.f. Coleman) instead of discs and annuli.
